Experimental Relevance

Nonlinear Optics
Bose Einstein Condensates (BECs)

Paradigm for competition between randomness and Nonlinearity a Fundamental Question
Outline

- Introduction
- Rigorous results
- Perturbation Theory
- Numerical results and Effective Noise Theories
- Scaling Theory
- Summary
- Open Questions
The Nonlinear Schrödinger (NLS) Equation

\[ i \frac{\partial}{\partial t} \psi = \mathcal{H}_0 \psi + \beta |\psi|^2 \psi \]

1D lattice version

\[ \mathcal{H}_0 \psi(x) = -\left( \psi(x+1) + \psi(x-1) \right) + \varepsilon(x) \psi(x) \]

1D continuum version with no randomness, integrable

\[ \mathcal{H}_0 \psi(x) = -\frac{1}{2} \frac{\partial^2}{\partial x^2} \psi(x) + \varepsilon(x) \psi(x) \]

\( \mathcal{E} \) random \quad \rightarrow \quad \mathcal{H}_0 \quad \text{Anderson Model}
\[ \beta = 0 \implies \text{localization} \]

Does Localization Survive the Nonlinearity???
Does Localization Survive the Nonlinearity???

1. Yes, if there is spreading the magnitude of the nonlinear term decreases and localization takes over.

2. No, may depend on realizations or on $\beta$ found in numerical calculations.

3. No, the NLSE is a chaotic dynamical system. Will it remain chaotic for all densities??

4. No?, but localization asymptotically preserved beyond some front that is logarithmic in time
Point 4, conjectured by Wang and Zhang in the limit of strong disorder:

given \( \varepsilon = \text{hopping} + \beta \quad \delta > 0, A > 0 \)

tail beyond \( j_0 \) of weight \( < \delta \)

there exist \( C, \varepsilon(A), K > A^2 \)

So that for all \( t \leq \left( \frac{\delta}{C} \right) \varepsilon^{-A}, \varepsilon < \varepsilon(A) \)

\[ \ln t \sim A_f \]

With probability \( 1 - \exp \left( -\frac{j_0}{K} \varepsilon^{-2K/C} \right) \)

Tail beyond \( j_0 + K \) of weight \( < 2\delta \)

Conjecture Logarithmic front \( j_0 + K_f \quad K_f > A^2 \)

Perturbation theory supports this conjecture for any disorder
Point 4 also in agreement with work of Basko (perturbation theory).
Selecting a type of dominant excitations

***Bourgain and Wang

\[ \beta \Rightarrow \varepsilon \left| 1+ \right| x \left\| -\alpha \right. \]

Spreading slower than any power of \( t \)
1. A perturbation expansion in $\beta$ was developed
2. Secular terms were removed
3. A bound on the general term was derived
4. Perturbation theory was used to obtain a controlled numerical solution
5. A bound on the remainder was obtained, indicating that the series is asymptotic.
6. For limited time tending to infinity for small nonlinearity, front logarithmic in time $x_f \propto \ln t$
7. Improved for strong disorder
8. Posed problems in Linear Anderson Localization for example combinations of eigen-energies (in denominators)
Bound on the remainder

\[ \beta^N Q_n = \text{remainder} \]
\[ |\beta^N Q_n| \leq C \text{e}^{-\gamma |x_n|} \]
\[ C \propto \beta^N e^{cN^2} \]
\[ \lim_{\beta \to 0} |\beta^N Q_n| / \beta^{N-1} = 0 \quad \rightarrow \quad \text{Asymptotic} \]

Remainder to expansion in terms of exponentially localized Functions negligible for
\[ x > x_f \sim \frac{1}{\gamma} \ln t \]

Defines front \( x_f \)

Main problem divergence of \( C \) with \( N \)
Numerical Simulations

- In regimes relevant for experiments looks that localization takes place
- Spreading for long time (Shepelyansky, Pikovsky, Mulansky, Molina, Flach, Koupidakis, Komineas, Krimer, Laptyeva, Bodyfelt)
- We do not know the relevant space and time scales
- All results in Split-Step
- No control (but may be correct in some range)
- Supported by various heuristic arguments
FIG. 2: (color online) Probability distribution $w_n$ over lattice sites $n$ at $W = 4$ for $\beta = 1$, $t = 10^8$ (top blue/solid curve) and $t = 10^5$ (middle red/gray curve); $\beta = 0$, $t = 10^5$ (bottom black curve; the order of the curves is given at $n = 500$). At $\beta = 0$ a fit $\ln w_n = -(\gamma|n| + \chi)$ gives $\gamma \approx 0.3$, $\chi \approx 4$. The values of $\log_{10} w_n$ are averaged over the same disorder realizations as in Fig. 1.

FIG. 3: (color online) Same as in Fig. 2 but with $W = 2$. At $\beta = 0$ a fit $\ln w_n = -(\gamma|n| + \chi)$ gives $\gamma \approx 0.06$, $\chi \approx -3$. The values of $\ln w_n$ are averaged over the same disorder realizations as in Fig. 1.

Slope does not change (contrary to Fermi-Pasta-Ulam)
\log < x^2 >

$2 \log x \lesssim 2 \log x \lesssim 2 \log x$
Effective Noise Theories

• D. Shepeyansky and A. Pikovsky
• S. Flach, Ch. Skokos, D.O. Krimer, S. Komineas
• E. Michaely and SF
\[ \psi(x, t) = \sum_m c_m(t) e^{-iE_m t} u_m(x) \]

\[ i \frac{\partial}{\partial t} c_n = \beta \sum_{m_1, m_2, m_3} V_{n}^{m_1, m_2, m_3} c_{m_1}^* c_{m_2} c_{m_3} e^{i(E_n + E_{m_1} - E_{m_2} - E_{m_3}) t} \]

Overlap

\[ V_{n}^{m_1, m_2, m_3} = \sum_x u_n(x) u_{m_1}(x) u_{m_2}(x) u_{m_3}(x) \]

\[ |V_{n}^{m_1 m_2 m_3}| \leq [\text{const}] e^{-\frac{1}{3} \gamma (|x_n - x_{m_1}| + |x_n - x_{m_2}| + |x_n - x_{m_3}|)} \]

of the range of the localization length \( \xi \)
\[ i \frac{\partial}{\partial t} c_n = \beta \sum_{m_1, m_2, m_3} V_{n}^{m_1, m_2, m_3} c_{m_1}^* c_{m_2} c_{m_3} e^{i(E_n + E_{m_1} - E_{m_2} - E_{m_3})t} \]

Assume \( |c_{m_1}^2| \approx |c_{m_2}^2| \approx |c_{m_3}^2| \approx \rho \) initially, \( |c_n^2| \ll \rho \)

\[ \frac{\partial}{\partial t} c_n \approx \beta \rho^{3/2} Pf_n(t) = F_n(t) \]

Random uncorrelated

\[ P = C \beta \xi^\alpha \rho \]

Number of resonant states

leading to \( \langle x^2 \rangle \sim t^{1/3} \)

It was checked effective noise holds for realizations with sub-diffusion
Equilibrium \[ \langle |c_n|^2 \rangle = \rho \]

Equilibration time \[ T_{eq} \]

\[ D = C \frac{\xi^2}{T_{eq}} = CB \rho^4 \]

For diffusion \[ \langle x^2 \rangle = D t \] but \[ \langle x^2 \rangle \propto \frac{1}{\rho^2} \]

\[ \frac{1}{\rho^2} = CB \rho^4 t \]

\[ \langle x^2 \rangle = C_1 \frac{1}{\rho^2} = C \left[ \beta \xi \nu t \right]^{1/3} \]

Consistent \[ T_{eq} \sim t^{2/3} \ll t \]
Can it go on forever? What happens when nearly no weight in localization volume?

\[ P = C \beta \xi^\alpha \rho \]

Number of resonant states

numerically \[ 1.85 < \alpha < 2.56 \]

For the theory to be valid require that the number of resonant terms larger then a number of order unity otherwise NO effective noise. Requires:

\[ 1 < P = (\ldots) \xi^\alpha \rho \quad \Rightarrow \quad t < t_* \sim \xi^\delta \]

\[ 7.4 < \delta < 10.24 \]
Scaling Properties of Chaos
Arkady Pikovsky

Model for the region of large amplitude

Competition

Spreading → effective number of degrees of freedom increases → chaos enhanced

Spreading_ → amplitude decreases → regularity enhanced

Who wins??
\[ i \frac{d}{dt} \psi(x) = -J \left( \psi(x+1) + \psi(x-1) \right) + \varepsilon(x)\psi(x) + |\psi(x)|^2 \psi(x) \]

\[ X \quad \text{integer} \quad 1 \leq x \leq L \quad J = \frac{1}{1+W} \quad -JW \leq \varepsilon \leq JW \]

\( \psi(x) \) \quad Are dynamical variables

Initial data, nearly homogeneous spreading in space

Growth of deviations

\[ \delta \psi(t) \sim \delta \psi(t = 0) e^{\lambda t} \quad \lambda \quad \text{Largest Lyapunov exponent} \]

\( \lambda > 0 \rightarrow \text{Chaos} \)

Is it possible that chaos disappears?
Divide chain into intervals of length $L_0$. Number of intervals $\frac{L}{L_0}$.

Assuming independence, if intervals large enough
The probability to be regular: $L_0 \gg \xi$

Regularity=all orbits regular

$$p_{\text{reg}}(\rho, W, L) = p_{\text{reg}}(\rho, W, L_0)^{L/L_0}$$

Density

$$\rho = \frac{N}{L}$$

$$N = \sum_{x=1}^{L} |\psi(x)|^2$$

$$R(\rho, W) \equiv p_{\text{reg}}(\rho, W, L)^{1/L} = p_{\text{reg}}(\rho, W, L_0)^{1/L_0}$$

independent of $L$
Scaling

\[ P_0(\rho, W) \equiv P_{\text{reg}}(\rho, W, L_0) \]

define \( Q \) by \( P_0 = \frac{1}{1 + 1/Q} \)

Regular limit \( P_{\text{reg}} \to 1, P_0 \to 1 \iff Q \to \infty \)

\( \rho \to 0 \) \quad \( W \to 0 \) \quad Singular limits

Assume scaling function \( Q(\rho, W) = \frac{1}{W^\alpha} q\left(\frac{\rho}{W^\beta}\right)\)
Singular limits

small  \( x \)  \( q \sim c_1 x^{-\varsigma} \)

large  \( x \)  \( q \sim c_2 x^{-\eta} \)

Numerical fit

\[ \alpha = \beta \approx 1.75 = \frac{7}{4} \]
\[ \varsigma \approx 2.25 = \frac{9}{4} > 1 \]
\[ \eta \approx 5.2 \]
\[ c_1 \approx 2.5 \cdot 10^{-7} \]
\[ c_2 \approx 1.8 \cdot 10^{-18} \]

very small !!!
What can one conclude from the scaling??

\[ \rho \to 0 \iff x \to 0 \implies Q \to \infty \]

\[ P_0 = \frac{1}{1+1/Q} \approx 1 - \frac{1}{Q} \to 1 \]

\[ p_{\text{reg}}(\rho, W, L) = p_0(\rho, W)^{L/L_0} = \left[ 1 - \frac{1}{Q} \right]^{L/L_0} \]

\[ P_{\text{ch}} = 1 - P_{\text{reg}} \approx -\ln P_{\text{reg}} \approx \frac{L}{L_0 Q} = \frac{L}{L_0} W^\alpha \frac{1}{q} \]

\[ Q \text{ scaling function} \]

\[ P_{\text{ch}} = 1 - \frac{L}{c_1 L_0} W^{\alpha(1-\varsigma)} \rho^\varsigma \]

density \[ \rho = \frac{N}{L} \text{ with } N = \sum_{x=1}^{L} |\psi(x)|^2 \]

\[ P_{\text{ch}} = \frac{1}{c_1} \frac{L^{1-\varsigma}}{L_0} W^{\alpha(1-\varsigma)} N^\varsigma \]

Using exponents found here

\[ P_{\text{ch}} \approx \frac{N^{9/4}}{c_1 L_0 W^{35/16}} L^{-5/4} \]
Large system limit

\[ P_{ch} \approx \frac{N^{9/4}}{c_1 L_0 W^{35/16}} L^{-5/4} \rightarrow 0 \]

\[ L \rightarrow \infty \quad \text{and} \quad N \quad \text{fixed} \]

What the scale required to see it??

set minimal probability for chaos to be effective \( P_{\text{min}} \)

\[ L_{\text{max}} = N^{\frac{\varsigma}{\varsigma - 1}} W^{-\alpha} \left( P_{\text{min}} L_0 c_1 \right)^{-\frac{1}{\varsigma - 1}} \]

For \( P_{\text{min}} \approx 0.05 \)

and parameters used in numerical calculations \( L_{\text{max}} \approx 10^5 \)
If no additional singularity in $Q$

Spreading

No chaos

Localization?
Emerging Picture

- For small nonlinearity initially no spreading
- For strong nonlinearity some part does not spread
- For some nonlinearity wide regime of sub-diffusion
- Asymptotic spreading at most logarithmic (shown for limited time):
  a. perturbation theory
  b. rigorous results in the limit of strong disorder
- Unlikely that sub-diffusion continues forever:
  a. scaling theory showing that as result of spreading system becomes regular for an increasing fraction of realizations
  b. Effective noise “theories” indicate that as a result of spreading noise Decays
  c. More realizations quasiperiodic (Aubry)

Coherent picture for various regimes? What is the relevant time scale for asymptotics?

What of this can be established rigorously??
Possible asymptotic behavior

- Localization
- Logarithmic spread
- Sub-diffusion
- Spread to some distance depending on realization of disorder
