Magnetic Fields

I'll mainly discuss

$$H(\vec{a}, V) = (-i\vec{\nabla} - \vec{a})^2 + V$$

In connection with understanding Kato's work on what I named Kato's inequality, I first proved (for Bose statistics) that

$$\inf \text{spec}(H(\vec{a}, V)) \geq \inf \text{spec}(H(\vec{a} = 0, V))$$

This led me to conjecture and then prove, with an assist from Ed Nelson, that

$$\left| e^{-tH(\vec{a}, V)} \varphi \right| \leq e^{-tH(\vec{a}=0, V)} |\varphi|$$

something I named diamagnetic inequalities.

In this regard, it should be mentioned that before working on magnetic fields, Yosi and Ira (without me!) wrote a seminal paper on constant electric fields including the Stark effect.

One lovely result is the Avron–Herbst formula,

$$H_o = p^2 + x_1 \Rightarrow e^{-itH_o} = e^{-itx_1} e^{-itp^2} e^{it^2 p_1} e^{-it^3/3}$$

a formula with interesting physics built into it.

Projections

Yosi and I found a counterexample for this in 1979.

The idea is the same as that behind the Bohm–Aharonov effect. If, due to an infinite V in the region where $B \neq 0$, the electron doesn't feel \vec{B} directly, it can still feel \vec{a} . But then $\langle \varphi, \vec{B} \cdot \vec{\sigma} \varphi \rangle = 0$ so one can't have opposite inequalities.

A Tale of Two
Projections

In trying to understand the integer quantum Hall effect, Thouless, Kohmoto, Nightingale, and den Nijs were able to compute the conductance due to a single non-degenerate band to a constant times an integer, which we called TKNN integers (Avron–Seiler–Simon–1983).

They had essentially rediscovered the Chern class.

Our paper includes an explicit formula that Yosi loved writing down:

$$n_j = \frac{i}{2\pi} \int \text{Tr}((dP_j)P_j(dP_j))$$

where $P_j(k)$ is the projection onto the j th base function at k and n_j is the TKNN integer.

TKNN Integers

In the proof, we needed to compute the homotopy groups of the set of compact self-adjoint operators with non-degenerate eigenvalues.

We did this with the exact sequence of a fibration. There is an interesting story behind our use of this tool.

We found a number of abstract results, for example, if $M_n(\mathbb{C})$ is the $n \times n$ complex Hermitian matrices with simple eigenvalues, the only non-trivial homotopy group is $\pi_2(M_n(\mathbb{C})) = \mathbb{Z}^{n-1}$, corresponding to $n - 1$ TKNN integers. For quaternion \mathbb{H} , the only low-dimensional nontrivial π is $\pi_4(M_n(\mathbb{H})) = \mathbb{Z}^{n-1}$.

- Our first joint paper (1977) studied analytic continuation of the band functions of periodic potentials in higher dimension. The one-dimensional case had been studied by Walter Kohn using ODE methods (and we also extended his work).
- A “homework problem” of Evans Harrell. He had studied asymptotics of the gaps in the spectrum of

$$-\frac{d^2}{dx^2} + 2\kappa \cos(2x)$$

where his formula had a constant involving integrals of Airy functions, and he asked what the constant value was. We found a new approach to the problem—a cute argument that led to a direct calculation of the constant.

To illustrate the depth of a simple pair of projections, I want to discuss a lovely result of Landau–Pollak, well known in the “signal community,” but which I only recently learned about. Even though it dates to 1961, when Yosi and I were kids, I’m hoping it is also new to him and that I can present this as a birthday bouquet.

Here is their result:
